There are three major aspects of antimicrobial resistance in foodborne pathogens: (1) the resistance to quinolones and cephalosporins in *Salmonella enterica*, and to quinolones and macrolides in *Campylobacter*, (2) multidrug-resistant clones of monophasic *Salmonella* Typhimurium-like organisms, (3) strains of Enterobacteriaceae, in particular *Escherichia coli*, either exhibiting resistance to beta (β)-lactam antibiotics or producing AmpC β -lactamases. Controlling antibiotic usage in food animals is necessary in order to reduce the incidence of resistant organisms. A single control measure is unlikely to limit the transmission of resistance through the food chain. Surveillance of resistance in humans and food animals is vital for measuring the long-term effectiveness of any control measure.
